

Finding the biggest number With a Counter(For Loop)

2) Imagine you are at a sporting event where people are doing the High Jump. You are given the data at the end of the event so you can put it into a program you are making. For our purposes here, every number will have to be input by hand and will be checked inside the loop. (Basically put a "user input" inside the loop to take in the new data). After you input the first number it will be stored as the biggest number. When you input your second number you will have to check if it is bigger than the first, if it is bigger store it as the biggest number. Imagine you are checking (inputting) 10 numbers for the highest number
Case 1) Input = 50,86,33,66,45,100,2,78,52,1
Output = 100
Case 2) 1000,555,951, 2,321,0,7,5,333,99
Output = 1000

1) I am given data(maybe this is an input)
2) put data into a variables
3) loop (we may need to put our input in here)
4) define a variable BiggestNumber and make the first variable equal to it
5) compare the biggest number to the current number
6) when you are done inputting numbers, print the BiggestNumber

Finding the biggest number With a Condition(While)
