- This code defines two methods in a controller class, one called "Index" and another called "GetInfoFromDB".
- The "Index" method returns a view that displays information retrieved from a database by calling the "GetInfoFromDB" method.
- The "GetInfoFromDB" method retrieves information about club members from a database and returns it as a list of objects of type "ClubMembers". Here's a step-by-step breakdown of what the "GetInfoFromDB" method does:

EMAIL: STUDYING@ITDCANADA.CA

- Overall, the "GetInfoFromDB" method is designed to retrieve information about club members from a database and return it as a list of objects of type "ClubMembers". This list can then be used to populate a data grid or perform other operations on the data. The "Index" method uses this list to display information about club members in our web page.
- Once you have finished writing the code, please run the program. The
 program will then take you to the "Index" view for the "ClubMember". If
 there is data in the database, it will be displayed in a table format.
 However, if there is no data in the database, you will not see any
 information displayed on the page.

ASP CLUB

To create an Edit action method in an ASP.NET MVC project using SQL Client:

- 1. Add a new HttpGet action method to the controller class, accepting an id parameter.
- 2. Inside the HttpGet action method, create a connection string to connect to the database.
- 3. Create a SQL query string to select the record with the specified id value from the ClubMembers table.
- 4. Create a new ClubMembers object to store the retrieved record data.
- 5. Using a SqlConnection object, connect to the database and execute the SQL query string to retrieve the record with the specified id.
- 6. Using a SqlDataReader object, read the retrieved record data and store it in the ClubMembers object.
- 7. Return the ClubMembers object to the corresponding view using the View method.

To create an Edit HTTP POST action method:

- 1. Add a new HttpPost action method to the controller class, accepting an ID and a ClubMembers object parameter.
- 2. Inside the HttpPost action method, create a connection string to connect to the database.
- 3. Create a SQL query string to update the record with the specified ID value in the ClubMembers table with the data in the ClubMembers object parameter.
- 4. Using a SqlConnection object, connect to the database and execute the SQL query string to update the record with the specified ID.
- 5. Redirect the user to the Index action method of the controller class.

In the Index view uncomment the /*id=item.PRIMARY KEY*/
And make it look like the one in the picture

```
Details.cshtml
                   ClubMembersController.cs
                                                               ClubMembers.cs
                                                                             HomeController.cs
     白
                      49
                         @Html.DisplayFor(modelItem => item.Level)
50
51
                     52
                         @Html.ActionLink("Edit", "Edit", new { id=item.MemberID }) |
53
                         @Html.ActionLink("Details", "Details", new { id=item.MemberID }) |
54
                         @Html.ActionLink("Delete", "Delete", new { id=item.MemberID})
                      56
57
```

Make the MemberID Read-only In the Edit View:

```
<h1>Edit</h1>
<h4>ClubMembers</h4>
<hr />
|<div class="row">
    <div class="col-md-4">
        <form asp-action="Edit">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <div class="form-group">
                <label asp-for="MemberID" class="control-label"></label>
               <input asp-for="MemberID" class="form-control" readonly />
                <span asp-validation-for="MemberID" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="FirstName" class="control-label"></label>
                <input asp-for="FirstName" class="form-control" />
                <span asp-validation-for="FirstName" class="text-danger"></span>
            </div>

ASP CLUB

• For "Details" there is only one action method. This is because the main goal of the "Details" action method is to display the details of a single club member. Since there are no other actions required in this case, there's no need for any additional methods.

- The HttpGet method retrieves the details of a single ClubMember by their ID from the database, and displays it in a view.
- The HttpPost method is called when the user confirms that they want to delete the ClubMember, and it deletes the member's record from the database.
- Both methods use a connection string to connect to the database, and execute a SQL query using a SqlCommand object. The HttpGet method reads the data using a SqlDataReader object, while the HttpPost method executes the query using cmd.ExecuteNonQuery().
- After the ClubMember is deleted, the HttpPost method returns the view of the Index page to display the updated list of ClubMembers.
